

Section 3.1: Measures of Center

In statistics we frequently need to perform operations on entire sets of data. One such operation is to add all values in a particular set together. We use a capital Greek sigma, Σ , to tell us to add everything together. So Σ Chris' test scores is $79 + 88 + 92 = 259$.

MATH 1107 Chris	Tests	Quizzes
	79	95
	88	86
	92	75
		89
		81

If the data set in question is obvious we may just write $\sum x$ where x represents every value in the data set. The sum of Chris' quiz scores is $\sum x = 95 + 86 + 75 + 89 + 81 = 426$.

Example 1 For Chris' test scores, $\sum x^2 = 79^2 + 88^2 + 92^2 = 22\,449$. In contrast, $(\sum x)^2 = (79 + 88 + 92)^2 = 259^2 = 67\,081$.

1 The Mean

Definition 1 The **mean** (also known as the **average**) in a set of n observations, x_1, x_2, \dots, x_n , is

$$\frac{\sum x_i}{n}. \quad (1)$$

Notation 1 The mean is always calculated as the sum of all observations divided by the number of observations. However we may want to indicate if the average comes from a sample or a population. We denote a sample average by \bar{x} and a population average by μ .

Example 2 The mean test score for Chris is $\mu = \frac{\sum x_i}{n} = \frac{79 + 88 + 92}{3} = \frac{259}{3} = 86.333$

Problem 2 Find the mean quiz score for Chris.

2 The Median

Definition 2 The **median** in a set of n observations that are ordered from smallest to largest is the middle observation (if n is odd) or the mean of the two middle observations (if n is even).

Example 3 To determine the median quiz score by Chris we first order the data from smallest to largest:

75, 81, 86, 89, 95

Now it is clear that the middle observation, and hence the median, is 86.

In the case of Chris' quiz scores the median and the mean are pretty close to each other. That won't always be the case!

Example 4 In CHEM 1101, Chris took six quizzes. His scores are: 81, 76, 82, 78, 12, 75. Again, we order the scores from smallest to largest.

12, 75, 76, 78, 81, 82

Here we average the two middle most observations and the median is $\frac{76+78}{2} = 77$. Just for fun, Chris' average quiz score in CHEM 1101 is $\mu = \frac{\sum x_i}{n} = \frac{12+75+76+78+81+82}{6} = \frac{202}{3} = 67.333$.

Problem 3 Here the median and mean are not very close to each other. Why?

Definition 3 A statistic is **resistant** if its value is not susceptible to extreme data points.

Take note that the median cuts the data set in half. That is, 50% of the data in the set falls below the median and 50% of the data falls above the median. This is not necessarily true about the average.

Example 5 Consider the player salaries for the 1997-1998 Chicago Bulls roster. Here the average salary is almost three times the median salary. This is due to Michael Jordan's salary which is significantly larger (though he was still underpaid!) than all other salaries.

Player	Salary
1 Michael Jordan	\$33,140,000
2 Ron Harper	\$4,560,000
3 Toni Kukoc	\$4,560,000
4 Dennis Rodman	\$4,500,000
5 Luc Longley	\$3,184,900
6 Scottie Pippen	\$2,775,000
7 Bill Wennington	\$1,800,000
8 Scott Burrell	\$1,430,000
9 Randy Brown	\$1,260,000
10 Robert Parish	\$1,150,000
11 Jason Caffey	\$850,920
12 Steve Kerr	\$750,000
13 Keith Booth	\$597,600
14 Jud Buechler	\$500,000
15 Joe Kleine	\$272,250
Average	\$4,088,711
Median	\$1,430,000

*Chicago Bulls Salaries
1997-1998 Season*

Remark 4 *The median is resistant. The mean is not resistant.*

3 The Mode

Definition 4 *The **mode** in a set of n observations is the value that occurs most frequently. A data set may have more than one mode. A data set with two modes is called **bimodal**. A data set with more than two modes is called **multi-modal**.*

Example 6 *There is no mode for Chris for either test scores or quiz scores. There is no value that appears more frequently than any other.*

Example 7 *The mode of number of games played for the 2012 Atlanta Hawks is 77. The mode for games started is 0.*

2011 Atlanta Hawks Team Statistics

One cannot compute a mean or median for qualitative data. It is possible to compute the mode for qualitative data.

Problem 5 A small bag of M&M's contained the following 20 candies. Find the mode for color of M&M.

red	green	blue	red	brown
red	brown	brown	orange	green
orange	orange	green	green	blue
green	green	brown	red	red

4 Missing Data

Example 8 Chris thought he only had three test scores in MATH 1107: 79, 88 and 92. Turns out, he misplaced one test. If his mean test score is 86, what score did Chris earn on the misplaced test?

Let x represent the missing test score. Using the formula for a mean, we know that

$$86 = \frac{79 + 88 + 92 + x}{4};$$

$$86 = \frac{259 + x}{4};$$

$$344 = 259 + x;$$

$$85 = x.$$

5 Trimmed Means

Definition 5 The $p\%$ trimmed mean is found by first trimming (removing) the top $p\%$ and bottom $p\%$ of the data set. Second, compute the mean of the remaining values.

Example 9 Let $S = \{3, 4, 4, 5, 6, 6, 7, 8, 15, 30\}$. The mean of S is $\frac{3+4+4+5+6+6+7+8+15+30}{10} = 8.8$. The 20% trimmed mean of S is $\frac{4+5+6+6+7+8}{6} = 6$. Note that the trimmed mean removes outliers.

6 The Proportion of Success

Definition 6 For a data set where each outcome can be classified as a success or failure, the **proportion of success** is a measure of center. The proportion of success is computed by the number of successes in the data set divided by the number of observations.

Example 10 A single die is rolled 10 times. The sequence of rolls is (1, 4, 5, 6, 3, 4, 5, 2, 3, 2). If a success is rolling an odd prime number then the proportion of success is $p = \frac{4}{10} = 0.4$.

Problem 6 If a success is rolling a perfect square, what is the proportion of success for the above sequence?

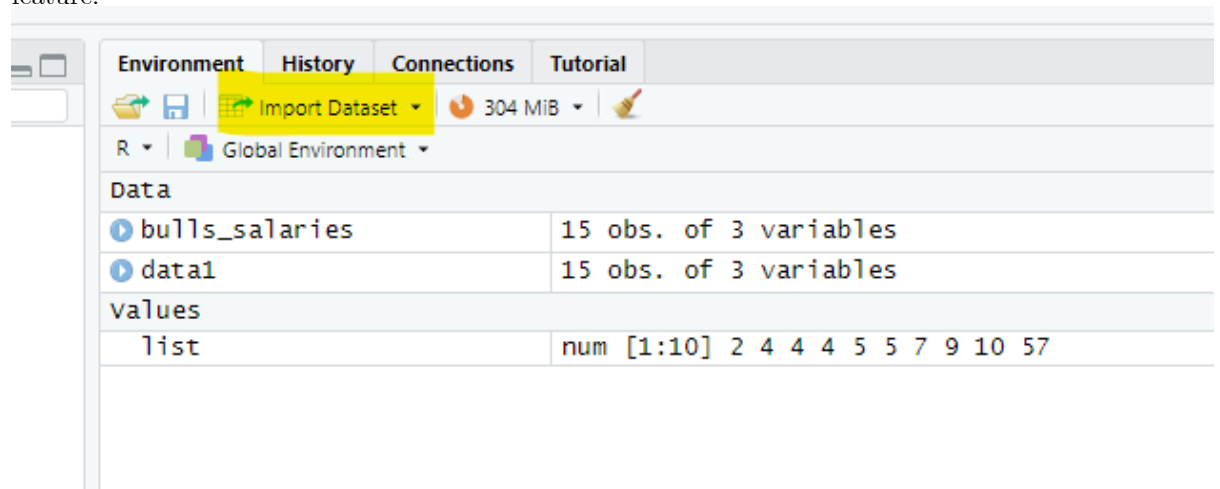

7 Using R to compute numerical statistics

We first create a vector of data for computing purposes. I have named my data set "list." Computing mean and median is as simple as it appears; call the command and indicate a data set. Note that trimmed mean requires an extra parameter. R Studio has no mode command. I've listed a couple of extra examples of commands for the next section.

Type 'demo()' for some demos, 'help()' for on-line help, or 'help.start()' for an HTML browser interface to help. Type 'q()' to quit R.

```
> list = c(2, 4, 4, 4, 5, 5, 7, 9, 10, 57)
> mean(list)
[1] 10.7
> median(list)
[1] 5
> mean(list, trim=0.1)
[1] 6
> var(list)
[1] 270.6778
> sd(list)
[1] 16.45229
> range(list)
[1] 2 57
> |
```

What if you have a dat set with more than one variable such as the Bull's Salaries? Load the Excel file into R using the import dataset button and browse feature.

and we get

	Rk	name	Salary
1	1	Michael Jordan	33140000
2	2	Ron Harper	4560000
3	3	Toni Kukoc	4560000
4	4	Dennis Rodman	4500000
5	5	Luc Longley	3184900
6	6	Scottie Pippen	2775000
7	7	Bill Wennington	1800000
8	8	Scott Burrell	1430000
9	9	Randy Brown	1260000
10	10	Robert Parish	1150000
11	11	Jason Caffey	850920
12	12	Steve Kerr	750000
13	13	Keith Booth	597600
14	14	Jud Buechler	500000
15	15	Joe Kleine	272000

To select one variable in a dataset we designate it with a "\$."

```

> summary(bulls_salaries)
