Section 17: Fourier Series: Trigonometric Series

Consider the following problem:

An undamped spring mass system has a mass of 2 kg attached to a spring with spring constant 128 N/m. The mass is driven by an external force f(t) = 2t for -1 < t < 1 that is 2-periodic so that f(t+2) = f(t) for all t > 0.

Common Models of Periodic Sources (e.g. Voltage)

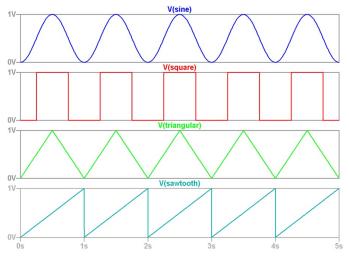

Figure: We'd like to solve, or at least approximate solutions, to ODEs and PDEs with periodic *right hand sides*.

Series Representations for Functions

The goal is to represent a function by a series

$$f(x) = \sum_{n=1}^{\infty}$$
 (some simple functions)

In calculus, you saw power series $f(x) = \sum_{n=0}^{\infty} a_n (x-c)^n$ where the simple functions were powers $(x-c)^n$.

Here, you will see how some functions can be written as series of trigonometric functions

$$f(x) = \sum_{n=0}^{\infty} (a_n \cos nx + b_n \sin nx)$$

We'll move the n = 0 to the front before the rest of the sum.

Some Preliminary Concepts

Suppose two functions f and g are integrable on the interval [a, b]. We define the **inner product** of f and g on [a, b] as

$$< f,g >= \int_{a}^{b} f(x)g(x) dx.$$

We say that f and g are **orthogonal** on [a, b] if

$$< f, g >= 0.$$

イロト 不得 トイヨト イヨト 二日

April 16, 2019

4/53

The product depends on the interval, so the orthogonality of two functions depends on the interval.

Properties of an Inner Product

Let f, g, and h be integrable functions on the appropriate interval and let c be any real number. The following hold

(ii)
$$< f, g + h > = < f, g > + < f, h >$$

(iii) < cf, g >= c < f, g >

(iv) $\langle f, f \rangle \geq 0$ and $\langle f, f \rangle = 0$ if and only if f = 0

Orthogonal Set

A set of functions $\{\phi_0(x), \phi_1(x), \phi_2(x), \ldots\}$ is said to be **orthogonal** on an interval [a, b] if

$$<\phi_m,\phi_n>=\int_a^b\phi_m(x)\phi_n(x)\,dx=0$$
 whenever $m
eq n.$

Note that any function $\phi(x)$ that is not identically zero will satisfy

$$<\phi,\phi>=\int_a^b\phi^2(x)\,dx>0.$$

Hence we define the square norm of ϕ (on [a, b]) to be

$$\|\phi\| = \sqrt{\int_a^b \phi^2(x) \, dx}.$$

An Orthogonal Set of Functions

Consider the set of functions

 $\{1, \cos x, \cos 2x, \cos 3x, \dots, \sin x, \sin 2x, \sin 3x, \dots\}$ on $[-\pi, \pi]$. Evaluate $(\cos(nx), 1)$ and $(\sin(mx), 1)$. Let not be any positive integer. By definition (Cos(nx), L) = J Cos(nx) · 1 dx $=\frac{1}{n}Sin(nx)\left|_{-\pi}^{\pi}=\frac{1}{n}Sin(n\pi)-\frac{1}{n}Sin(-n\pi)\right|$ =0-0=0

 $(\cos(nx), 1) = 0$ for all n = 1, 2, 3, ... $\cos(nx)$ is orthogonal to 1 for all n on $[-\pi, \pi]$. April 16, 2019 7/53

Similarly

$$\left\langle S_{in}(mx), 1 \right\rangle = \int_{-\pi}^{\pi} S_{in}(mx) \cdot 1 \, dx = \frac{1}{M} C_{0s}(mx) \Big|_{-\pi}^{\pi}$$

$$= \frac{1}{M} C_{0s}(m\pi) - \frac{1}{M} C_{0s}(-m\pi)$$

Cosine is even so = 0 Cos(-0) = Cos0

LSin(mx), 1)=0 for all m, so Sin(mx) is orthogonal to 1 on [-π, π].

An Orthogonal Set of Functions

Consider the set of functions

 $\{1, \cos x, \cos 2x, \cos 3x, \dots, \sin x, \sin 2x, \sin 3x, \dots\}$ on $[-\pi, \pi]$.

It can easily be verified that

$$\int_{-\pi}^{\pi} \cos nx \, dx = 0$$
 and $\int_{-\pi}^{\pi} \sin mx \, dx = 0$ for all $n, m \ge 1$,

 $\int_{-\pi}^{\pi} \cos nx \, \sin mx \, dx = 0 \quad \text{for all} \quad m, n \ge 1, \quad \text{and}$

$$\int_{-\pi}^{\pi} \cos nx \, \cos mx \, dx = \int_{-\pi}^{\pi} \sin nx \, \sin mx \, dx = \begin{cases} 0, & m \neq n \\ \pi, & n = m \end{cases},$$

An Orthogonal Set of Functions on $[-\pi, \pi]$

These integral values indicated that the set of functions

 $\{1, \cos x, \cos 2x, \cos 3x, \dots, \sin x, \sin 2x, \sin 3x, \dots\}$

is an orthogonal set on the interval $[-\pi, \pi]$.

Key Point: This means that if we take any two functions f and g from this set. then

 $\int_{-\pi}^{\pi} f(x)g(x) \, dx = 0 \quad \text{if } f \text{ and } g \text{ are different functions!}$

Fourier Series

Suppose f(x) is defined for $-\pi < x < \pi$. We would like to know how to write *f* as a series **in terms of sines and cosines**.

Task: Find coefficients (numbers) a_0 , a_1 , a_2 ,... and b_1 , b_2 ,... such that¹

$$f(x)=\frac{a_0}{2}+\sum_{n=1}^{\infty}\left(a_n\cos nx+b_n\sin nx\right).$$

Fourier Series

$$f(x)=\frac{a_0}{2}+\sum_{n=1}^{\infty}\left(a_n\cos nx+b_n\sin nx\right).$$

The question of convergence naturally arises when we wish to work with infinite series. To highlight convergence considerations, some authors prefer not to use the equal sign when expressing a Fourier series and instead write

$$f(x) \sim \frac{a_0}{2} + \cdots$$

イロト 不得 トイヨト イヨト

April 16, 2019

12/53

Herein, we'll use the equal sign with the understanding that equality may not hold at each point.

Convergence will be address later.

Finding an Example Coefficient

Let's find the coefficient b_4 .

Start with the series $f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$, and multiply both sides by $\sin(4x)$.

$$f(x)\sin(4x) = \frac{a_0}{2}\sin(4x) + \sum_{n=1}^{\infty} (a_n\cos nx\sin(4x) + b_n\sin nx\sin(4x)).$$
Now, integrate both sides from $-\pi$ to π and assume that
the order of integration and summation can be swapped.

$$\int_{-\pi}^{\pi} f(x)\sin(4x)dx = \int_{-\pi}^{\pi} \frac{a_0}{2}\sin(4x)dx + \int_{-\pi}^{\pi} e^{-\pi} \sin(4x)dx + \int_{-\pi}^{\pi} e^{-\pi} e^{$$

$$\int_{n=1}^{\infty} \int_{-T}^{T} \int_{-T}^{T} (4x) dx + \int_{-T}^{T} \int_{-T}^{T$$

Recall $(4x)_{1} = 0$ (Cos(nx), Sin(4x)) = 0 for all n

April 16, 2019 14 / 53

э

イロン イ理 とく ヨン イヨン

We have

$$\int_{-TT}^{TT} f(x) \sin(4x) dx = \sum_{n=1}^{N0} b_n \int_{-TT}^{TT} \sin(nx) \sin(4x) dx$$

$$\int_{-TT}^{TT} \int_{-TT}^{0} (nx) \sin(4x) dx = \begin{cases} 0, & n \neq 4 \\ T, & n = 4 \end{cases}$$

The sum is

$$\int_{-\pi}^{\pi} f(x) \sin(4x) dx = 0 + 0 + 0 + \pi b_{y} + 0 + 0 + \dots$$

$$= \pi b_{y}$$

April 16, 2019 15 / 53

Finding Fourier Coefficients

Note that there was nothing special about seeking the 4th sine coefficient b_4 . We could have just as easily sought b_m for any positive integer *m*. We would simply start by introducing the factor sin(*mx*).

Moreover, using the same orthogonality property, we could pick on the *a*'s by starting with the factor cos(mx)—including the constant term since $cos(0 \cdot x) = 1$. The only minor difference we want to be aware of is that

$$\int_{-\pi}^{\pi}\cos^2(mx)\,dx=\left\{egin{array}{cc} 2\pi,&m=0\ \pi,&m\ge1\end{array}
ight.$$

Careful consideration of this sheds light on why it is conventional to take the constant to be $\frac{a_0}{2}$ as opposed to just a_0 .

The Fourier Series of f(x) on $(-\pi, \pi)$

The **Fourier series** of the function *f* defined on $(-\pi, \pi)$ is given by

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx).$$

Where

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx,$$

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx dx, \text{ and}$$

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx dx$$
