Section1.1: Definitions and Terminology

Suppose $y = \phi(x)$ is a differentiable function. We know that $dy/dx = \phi'(x)$ is another (related) function.

For example, if $y = \cos(2x)$, then y is differentiable on $(-\infty, \infty)$. In fact,

$$\frac{dy}{dx} = -2\sin(2x).$$

Even dy/dx is differentiable with $d^2y/dx^2 = -4\cos(2x)$. Note that

$$\frac{d^2y}{dx^2} + 4y = 0.$$

$$-4\cos(2x) + 4\cos(2x) = 0 \quad \checkmark$$

Differential Equation

The equation

$$\frac{d^2y}{dx^2} + 4y = 0.$$

is an example of a **differential equation**.

Questions: If we only started with the equation, how could we determine that $\cos(2x)$ satisfies it? Also, is $\cos(2x)$ the only possible function that y could be?

Definition

A **Differential Equation** is an equation containing the derivative(s) of one or more dependent variables, with respect to one or more indendent variables.

Independent Variable: will appear as one that derivatives are taken with respect to.
Dependent Variable: will appear as one that derivatives are taken of.

$$\frac{dy}{dx} \leftarrow \text{depend.}$$

$$\uparrow \text{indepen}$$

$$\frac{du}{dt} \leftarrow \text{depend.}$$

$$\uparrow \text{indep.}$$

$$\frac{dx}{dr} \leftarrow \text{dep}$$

$$\uparrow \text{indep.}$$

Classifications

Type: An **ordinary differential equation (ODE)** has exactly one independent variable[1]. For example

$$\frac{dy}{dx} - y^2 = 3x, \quad \text{or} \quad \frac{dy}{dt} + 2\frac{dx}{dt} = t, \quad \text{or} \quad y'' + 4y = 0$$

A **partial differential equation (PDE)** has two or more independent variables. For example

$$\frac{\partial y}{\partial t} = \frac{\partial^2 y}{\partial x^2}, \quad \text{or} \quad \frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} = 0$$

---

[1] These are the subject of this course.

Classifications

Order: The order of a differential equation is the same as the highest order derivative appearing anywhere in the equation.

$$\frac{dy}{dx} - y^2 = 3x \qquad \text{1}^{st} \text{ order}$$

$$y''' + (y')^4 = x^3 \qquad \text{3}^{rd} \text{ order}$$

$$\frac{\partial y}{\partial t} = \frac{\partial^2 y}{\partial x^2} \qquad \text{2}^{nd} \text{ order}$$

Notations and Symbols

We'll use standard derivative notations:

$$\text{Leibniz:} \quad \frac{dy}{dx}, \quad \frac{d^2y}{dx^2}, \quad \ldots \quad \frac{d^ny}{dx^n}, \quad \text{or}$$

$$\text{Prime \& superscripts:} \quad y', \quad y'', \quad \ldots \quad y^{(n)}.$$

Newton's **dot notation** may be used if the independent variable is time. For example if s is a position function, then

$$\text{velocity is } \frac{ds}{dt} = \dot{s}, \quad \text{and acceleration is } \frac{d^2s}{dt^2} = \ddot{s}$$

Notations and Symbols

An nth order ODE, with independent variable x and dependent variable y can always be expressed as an equation

$$F(x, y, y', \ldots, y^{(n)}) = 0$$

where F is some real valued function of $n + 2$ variables.

Normal Form: If it is possible to isolate the highest derivative term, then we can write a **normal form** of the equation

$$\frac{d^n y}{dx^n} = f(x, y, y', \ldots, y^{(n-1)}).$$

Ex 1 $\dfrac{dy}{dx} - y^2 = 3x$

$\Rightarrow$ $\underbrace{\dfrac{dy}{dx} - y^2 - 3x}_{F(x, y, y')} = 0$

In normal form $\dfrac{dy}{dx} = \underbrace{y^2 + 3x}_{f(x,y)}$

Notations and Symbols

If $n = 1$ or $n = 2$, an equation in normal form would look like

$$\frac{dy}{dx} = f(x, y) \quad \text{or} \quad \frac{d^2 y}{dx^2} = f(x, y, y').$$

Differential Form: A first order equation may appear in the form

$$M(x, y)\, dx + N(x, y)\, dy = 0$$
