Section 5: First Order Equations Models and Applications

A Classic Mixing Problem If we are tracking the amount *A* of some substance (e.g. salt) disolved in some fluid in which we know the flow rates at which fluid is entering (r_i) and leaving (r_o) a receptacle, the initial volume V(0) of fluid, and the substance concentration of the inflow c_i , then for a **well mixed** solution

$$\frac{dA}{dt}=r_i\cdot c_i-r_o\frac{A}{V}.$$

Here $V(t) = V(0) + (r_i - r_o)t$. This equation is first order linear $\frac{dA}{dt} + \frac{r_o}{V}A = r_ic_i$

There is nothing precluding one of the coefficients such as r_o , r_i or c_i from being a nonconstant function of time.

Solve the Mixing Problem

A tank originally contains 500 gallons of pure water. Brine containing 2 pounds of salt per gallon is pumped in at a rate of 5gal/min. The well mixed solution is pumped out at the same rate. Find the amount of salt A(t) in pounds at the time t. Find the concentration of the mixture in the tank at t = 5 minutes.

We determined that

 $r_i = 5 \text{ gal/min}, c_i = 2 \text{ lb/gal}, r_o = 5 \text{ gal/min}, V(0) = 500 \text{ gal},$

$$A(0) = 0, \text{ and } c_0 = \frac{A}{500}. \qquad \forall (t_0 = 500 + (s - s)t = 500)$$
$$\frac{JA}{dt} + f_0 c_0 = f_0 c_0^{-1}$$

February 8, 2019 2 / 49

$$\frac{dA}{dt} + S\left(\frac{A}{500}\right) = S \cdot Z \qquad A(0) = 0$$

$$\frac{dA}{dt} + \frac{1}{100}A = 10 \qquad P(t) = \frac{1}{100}$$

$$\mu = e \qquad = e^{100} t$$

$$\frac{d}{dt}\left(e^{\frac{1}{100}t}A\right) = 10 e^{\frac{1}{100}t}$$

$$e^{\frac{1}{100}t}A = \int 10 e^{\frac{1}{100}t} dt$$

$$= \frac{1}{10}\left(e^{\frac{1}{100}t}A\right) = 10 e^{\frac{1}{100}t} dt$$

February 8, 2019 3 / 49

・ロト・西ト・モン・モー シック

February 8, 2019 4 / 49

At
$$t=5$$
 minutes $\frac{-1}{100} \cdot 5$
 $C(5) = \frac{1000 - 1000 \ e^{-100}}{500} \approx 0.0975 \frac{10}{500}$

Note that in the long run the concentration

$$\lim_{t \to \infty} C(t) = \lim_{t \to \infty} \frac{1000 - 1000 e^{-t_{oot}}}{500}$$

$$= \frac{1000}{500} = 2 \quad \frac{16}{300}$$

February 8, 2019 5 / 49

・ロト・西ト・モン・モー シック

$$r_i \neq r_o$$

Suppose that instead, the mixture is pumped out at 10 gal/min. Determine the differential equation satisfied by A(t) under this new condition.

$$\Gamma_{i} = S \frac{get}{mn} \quad C_{i} = 2 \frac{16}{9et} \qquad \Gamma_{0} = 10 \frac{get}{min}$$

$$V(t) = V(0) + (\Gamma_{i} - \Gamma_{0})t = 500 + (S - 10)t = 500 - 5t$$

$$C_{0} = \frac{A}{V} = \frac{A}{500 - 5t}$$

$$\frac{dA}{dt} + \Gamma_{0}C_{0} = \Gamma_{i}C_{i}$$

February 8, 2019 7 / 49

$$\frac{dA}{dt}$$
 + 10 $\left(\frac{A}{500-5t}\right)$ = 5.2

$$\frac{dA}{dt} + \frac{2}{100-t} A = 10$$

This is only valid for 0 < t < 100. Note that V(100) = 500 - 5(100) = 0. The volume is zero (tank is empty) at 100 minutes.

A Nonlinear Modeling Problem

A population P(t) of tilapia changes at a rate jointly proportional to the current population and the difference between the constant carrying capacity¹ M of the environment and the current population. Determine the differential equation satsified by P.

rate of change
$$\frac{dP}{dt}$$
 is proportional to P and
proportional to M-P.
 $\frac{dP}{dt} = kP(M-P)$ for some constant of
proportionality k.

¹The carrying capacity is the maximum number of individuals that the environment can support due to limitation of space and resources.

Logistic Differential Equation

The equation

$$\frac{dP}{dt} = kP(M-P), \quad k, M > 0$$

is called a logistic growth equation.

Solve this equation² and show that for any $P(0) \neq 0$, $P \rightarrow M$ as $t \rightarrow \infty$.

Let
$$P(0) = P_0$$
. The ODT is separable

$$\frac{dP}{dt} = k P(M-P) \Rightarrow \frac{1}{P(M-P)} \frac{dP}{dt} = k$$

$$\int \frac{1}{P(M-P)} dP = \int k dt$$

²The partial fraction decomposition

$$\frac{1}{P(M-P)} = \frac{1}{M} \left(\frac{1}{P} + \frac{1}{M-P} \right)$$

is useful.
