Section 5.3: Gaussian Quadrature

Here we are going to approximate the integral I(f) by the new *rule* called **Gaussian Quadrature**. The integration formula will be given by

$$I_n(f) = \sum_{j=1}^n w_j f(x_j)$$

where the numbers $\{w_1, \ldots, w_n\}$ are called the **weights** and $\{x_1, \ldots, x_n\}$ are called the **nodes**.

Main Idea: The weights and nodes are chosen so that $I_n(p) = I(p)$ exactly, for p(x) any polynomial of degree as high as possible.

Gaussian Quadrature: n = 1 Case

When n = 1, the formula becomes

$$l_1(f) = \sum_{j=1}^{1} w_j f(x_j) = w_1 f(x_1).$$

There is one weight w_1 and one node x_1 .

We determined that $w_1 = 2$ and $x_1 = 0$ giving the l_1 rule

$$\int_{-1}^{1} f(x) \, dx \approx l_1(f) = 2f(0).$$

イロト イポト イヨト イヨト

Gaussian Quadrature: n = 2 Case

When n = 2, the formula becomes

$$I_2(f) = \sum_{j=1}^2 w_j f(x_j) = w_1 f(x_1) + w_2 f(x_2).$$

There are two weights $\{w_1, w_2\}$ and two nodes $\{x_1, x_2\}$.

We determined that $w_1 = w_2 = 1$ with $x_1 = -\frac{1}{\sqrt{3}}$ and $x_2 = \frac{1}{\sqrt{3}}$. This gives the rule

$$\int_{-1}^{1} f(x) dx \approx l_2(f) = f\left(-\frac{1}{\sqrt{3}}\right) + f\left(\frac{1}{\sqrt{3}}\right).$$

March 30, 2016 3 / 14

Gaussian Quadrature:
$$I_2(f) = f\left(-\frac{1}{\sqrt{3}}\right) + f\left(\frac{1}{\sqrt{3}}\right)$$

Use $l_2(f)$ to approximate $\int_{-1}^{1} \frac{dx}{1+x^2}$. Compare the result to the true value $\frac{\pi}{2}$.

$$f(x) = \frac{1}{1+x^2}$$
 (the integrand)

$$I_{2}(f) = f\left(\frac{-1}{\sqrt{3}}\right) + f\left(\frac{1}{\sqrt{3}}\right)$$
$$= \frac{1}{1 + \left(\frac{-1}{\sqrt{3}}\right)^{2}} + \frac{1}{1 + \left(\frac{1}{\sqrt{3}}\right)^{2}} = \frac{1}{1 + \frac{1}{3}} + \frac{1}{1 + \frac{1}{3}} = \frac{3}{4} + \frac{3}{4}$$
$$= \frac{6}{4} = \frac{3}{2}$$

Gaussian Quadrature for n > 2

We would insist that the formula $I_n(p)$ is exact for $p(x) = 1, x, x^2, ..., x^{2n-1}$. ¹ We'll get a nonlinear system of 2n equations

$$w_{1} + w_{2} + \dots + w_{n} = 2$$

$$w_{1}x_{1} + w_{2}x_{2} + \dots + w_{n}x_{n} = 0$$

$$w_{1}x_{1}^{2} + w_{2}x_{2}^{2} + \dots + w_{n}x_{n}^{2} = \frac{2}{3}$$

$$\vdots \qquad \vdots$$

$$w_{1}x_{1}^{2n-2} + w_{2}x_{2}^{2n-2} + \dots + w_{n}x_{n}^{2}2n - 2 = \frac{2}{2n-1}$$

$$w_{1}x_{1}^{2n-1} + w_{2}x_{2}^{2n-1} + \dots + w_{n}x_{n}^{2n-1} = 0$$

¹This is 2*n* conditions for the 2*n* unknowns $\{w_1, \ldots, w_n\}$ and $\{x_1, \ldots, x_n\}$. $\forall \forall x_1, \ldots, x_n\}$.

Gaussian Quadrature for n > 2

Fortunately, solutions for various *n* values are known. Table 5.7 (pg. 223) in Atkinson and Han shows the weights and nodes for n = 2, 3, ..., 8.

For example, the weights and nodes for $I_3(f)$ are

$$w_1 = \frac{5}{9}, \quad w_2 = \frac{8}{9} \text{ and } w_3 = \frac{5}{9}$$

 $x_1 = -\sqrt{\frac{3}{5}}, \quad x_2 = 0, \text{ and } x_3 = \sqrt{\frac{3}{5}}.$

Read the table carefully in the text. The weights for corresponding nodes are aligned in the table.

Example for n = 3

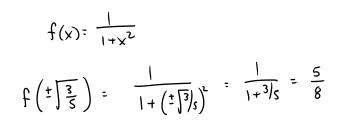

Use $I_3(f)$ to approximate $\int_{-1}^1 \frac{dx}{1+x^2}$. Compare the result to the true value $\frac{\pi}{2}$.

$$X_1 = -\sqrt{3} x_3 = \frac{5}{4}$$
 $X_2 = 0 \quad W_2 = \frac{8}{4} \quad X_3 = \sqrt{\frac{3}{5}} \quad W_3 = \frac{5}{4}$

March 30, 2016

8/14

$$I_{3}(f) = \frac{5}{9}f(-\sqrt{3}) + \frac{8}{9}f(0) + \frac{5}{9}f(\sqrt{3})$$

$$f(\delta) = \frac{1}{1+\delta^{2}} = 1$$

$$\int_{-1}^{1} \frac{dx}{1+y^{2}} dx \approx T_{3}(f) = \frac{5}{9} \cdot \frac{5}{8} + \frac{9}{9} \cdot 1 + \frac{5}{9} \cdot \frac{5}{8}$$

$$= \frac{25}{72} + \frac{64}{72} + \frac{25}{72} = \frac{114}{72}$$

$$= \frac{57}{36} = 1.58\overline{33}$$

$$\overline{\frac{\pi}{2}} = 1.570716$$

Other Intervals

Suppose we wish to evaluate

$$\int_a^b f(x)\,dx.$$

We'd like a change of variables $x \to t$ so that $-1 \le t \le 1$ when $a \le x \le b$. We already know that

$$t = \frac{2}{b-a}(x-a) - 1$$
, i.e. $x = \frac{b-a}{2}(t+1) + a$

does the trick. This gives $dx = \frac{b-a}{2}dt$ so that

$$\int_{a}^{b} f(x) \, dx = \frac{b-a}{2} \int_{-1}^{1} g(t) \, dt$$

where

$$g(t) = f\left(\frac{b-a}{2}(t+1) + a\right).$$
March 30, 2016 10/14

Example Use $I_2(f)$ to approximate $\int_{-1}^{1} \sqrt{x} \, dx \qquad \text{are onl } b=1$ $X = \frac{b-a}{2} (t+1) + a = \frac{1-b}{2} (t+1) + 0 = \frac{1}{2} (t+1)$ $f(x) = \sqrt{x} \Rightarrow g(t) = \sqrt{\frac{1}{2}(t+1)}$ $\int \overline{Jx} \, dx = \frac{1-9}{2} \int \overline{J_{\frac{1}{2}(t+1)}} \, dt = \frac{1}{2} \int \overline{J_{\frac{1}{2}(t+1)}} \, dt$

Comparison of Methods

$$\int_{0}^{1} \sqrt{x} \, dx = \frac{2}{3} = 0.66667$$
$$l_{2}(f) = f\left(-\frac{1}{\sqrt{3}}\right) + f\left(\frac{1}{\sqrt{3}}\right) = 0.67389, \quad f(t) = \frac{1}{2}\sqrt{\frac{t+1}{2}}$$
$$T_{4}(f) = \frac{1}{8}\left[\sqrt{0} + 2\sqrt{\frac{1}{4}} + 2\sqrt{\frac{1}{2}} + 2\sqrt{\frac{3}{4}} + \sqrt{1}\right] = 0.64328$$
$$S_{4}(f) = \frac{1}{12}\left[\sqrt{0} + 4\sqrt{\frac{1}{4}} + 2\sqrt{\frac{1}{2}} + 4\sqrt{\frac{3}{4}} + \sqrt{1}\right] = 0.65653$$

The errors are

 $I - I_2 = -0.00722$, $I - T_4 = 0.02338$, and $I - S_4 = 0.01014$
