

Section 9: Method of Undetermined Coefficients

The context here is linear, constant coefficient, nonhomogeneous equations

$$a_n y^{(n)} + a_{n-1} y^{(n-1)} + \cdots + a_0 y = g(x)$$

where g comes from the restricted classes of functions

- ▶ polynomials,
- ▶ exponentials,
- ▶ sines and/or cosines,
- ▶ and products and sums of the above kinds of functions

Recall $y = y_c + y_p$, so we'll have to find both the complementary and the particular solutions!

Method of Undetermined Coefficients

$$a_n y^{(n)} + a_{n-1} y^{(n-1)} + \cdots + a_0 y = g(x)$$

To find a particular solution y_p , we

- ▶ classify the function g by its type,
- ▶ created an assumed form for the function y_p (of corresponding type) with unknown coefficients,
- ▶ use substitution into the ODE and matching of like terms to find the coefficients.

We find y_c using the characteristic equation (**do this first**), then our general solution

$$y = y_c + y_p.$$

When part of g solves the homogeneous equation...

$$y'' - y' = 3e^x$$

We tried to find y_p in the form $y_p = Ae^x$, but the process failed. The solution to the associated homogeneous equation

$$y_c = c_1 + c_2 e^x.$$

The problem here is that Ae^x is the same as $c_2 e^x$. The method can still be used, but the form of the particular solution has to be modified.

We'll consider cases

Using superposition as needed, begin with assumption:

$$y_p = y_{p_1} + \cdots + y_{p_k}$$

where y_{p_i} has the same **general form** as $g_i(x)$.

Case I: y_p as first written has no part that duplicates the complementary solution y_c . Then this first form will suffice.

Case II: y_p has a term y_{p_i} that duplicates a term in the complementary solution y_c . Multiply y_{p_i} by x^n , where n is the smallest positive integer that eliminates the duplication.

Case II Examples

Solve the ODE

$$y'' - 2y' + y = -4e^x$$

Constant coef. left, exponential right.

Looking for $y = y_c + y_p$.

Find y_c : $y'' - 2y' + y = 0$

Characteristic eqn

$$m^2 - 2m + 1 = 0$$

$$(m-1)^2 = 0 \Rightarrow m=1 \text{ repeated}$$

$$y_1 = e^x, y_2 = x e^x$$

$$y_c = C_1 e^x + C_2 x e^x$$

Find y_p : $g(x) = -4e^x$

1st Guess $y_p = Ae^x$ won't work, part of y_c

2nd $y_p = (Ae^x)x = Axe^x$ won't work, part of y_c

3rd $y_p = (Axe^x)x = Ax^2e^x$ This will work.

$$y_p' = Ax^2e^x + 2Ax e^x$$

$$\begin{aligned} y_p'' &= Ax^2e^x + 2Ax e^x + 2Ax e^x + 2Ae^x \\ &= Ax^2e^x + 4Ax e^x + 2Ae^x \end{aligned}$$

$$y_p'' - 2y_p' + y_p = -4e^x$$

$$Ax^2e^x + 4Ax\cancel{e^x} + 2A\cancel{e^x} - 2(Ax^2\cancel{e^x} + 2A\cancel{x}e^x) + Ax^2e^x = -4e^x$$

Collect like terms

$$x^2e^x(A - 2A + A) + x\cancel{e^x}(4A - 4A) + 2A\cancel{e^x} = -4e^x$$

$$2Ae^x = -4e^x$$

$$A = -2$$

$$\text{so } y_p = -2x^2e^x$$

The general solution $y = y_c + y_p$

$$y = C_1 e^x + C_2 x e^x - 2x^2 e^x$$

Find the form of the particular solution

$$y'' - 4y' + 4y = \sin(4x) + xe^{2x}$$

Find y_c : $y'' - 4y' + 4y = 0$ $m^2 - 4m + 4 = 0$
 $(m-2)^2 = 0$ $m = 2$ repeated
 $y_1 = e^{2x}$, $y_2 = xe^{2x}$

$$y_c = C_1 e^{2x} + C_2 x e^{2x}$$

To find the form of y_p , consider the subproblems

$$y'' - 4y' + 4y = \sin(4x) \quad \text{for } y_{p1}$$

and $y'' - 4y' + 4y = xe^{2x} \quad \text{for } y_{p2}$

$$y_c = C_1 e^{2x} + C_2 x e^{2x}$$

$$g_1(x) = \sin(4x)$$

$$y_{p1} = A \sin(4x) + B \cos(4x)$$

will work

$$g_2(x) = x e^{2x}$$

$$y_{p2} = (Cx + D) e^{2x} = Cx e^{2x} + D e^{2x}$$

Not right

$$y_{p2} = (Cx + D) x e^{2x} = Cx^2 e^{2x} + Dx e^{2x}$$

Nope!

$$y_{p2} = (Cx + D) x^2 e^{2x} = Cx^3 e^{2x} + Dx^2 e^{2x}$$

Yep!

$$y_p = A \sin(4x) + B \cos(4x) + Cx^3 e^{2x} + Dx^2 e^{2x}$$

Find the form of the particular solution

$$y''' - y'' + y' - y = \cos x + x^4$$

Find y_c : $y''' - y'' + y' - y = 0$ $m^3 - m^2 + m - 1 = 0$

$$(m-1)(m^2+1) = 0$$

$$m=1 \text{ or } m^2+1=0, m^2=-1$$

$$m = \pm i$$

$$\alpha=0, \beta=1$$

$$y_1 = e^x, \quad y_2 = e^{0x} \cos x, \quad y_3 = e^{0x} \sin x$$

$$y_c = C_1 e^x + C_2 \cos x + C_3 \sin x$$

To find y_p consider

$$y''' - y'' + y' - y = \cos x \quad \text{for } y_{p1}$$

$$y''' - y'' + y' - y = x^4 \quad \text{for } y_{p2}$$

$$g_1(x) = \cos x, \quad y_{p1} = A \cos x + B \sin x \quad \text{won't work}$$

$$\begin{aligned} y_{p1} &= (A \cos x + B \sin x) x \\ &= Ax \cos x + Bx \sin x \quad \checkmark \end{aligned}$$

$$g_2(x) = x^4 \quad y_{p2} = Cx^4 + Dx^3 + Ex^2 + Fx + G \quad \checkmark$$

$$y_p = Ax \cos x + Bx \sin x + Cx^4 + Dx^3 + Ex^2 + Fx + G$$

Solve the IVP

$$y'' - y = 4e^{-x} \quad y(0) = -1, \quad y'(0) = 1$$

We need $y = y_c + y_p$.

$$\text{Find } y_c: \quad y'' - y = 0 \quad m^2 - 1 = 0$$
$$(m-1)(m+1) = 0 \Rightarrow m = 1 \text{ or } m = -1$$

$$y_1 = e^x, \quad y_2 = e^{-x}$$

$$y_c = c_1 e^x + c_2 e^{-x}$$

$$\text{Find } y_p: \quad g(x) = 4e^{-x}, \quad y_p = (Ae^{-x})x = Ax e^{-x}$$

$$y_p = A x e^{-x}$$

$$y_p' = -A x e^{-x} + A e^{-x}$$

$$y_p'' = A x e^{-x} - A e^{-x} - A e^{-x} = A x e^{-x} - 2A e^{-x}$$

$$y_p'' - y_p = 4e^{-x}$$

$$A x e^{-x} - 2A e^{-x} - A x e^{-x} = 4e^{-x}$$

$$x e^{-x} (\underbrace{A - A}_0) + e^{-x} (-2A) = 4e^{-x}$$

$$-2A e^{-x} = 4e^{-x}$$

$$A = -2$$

$$y_p = -2x e^{-x}$$

Gen. soln. $y = C_1 e^x + C_2 e^{-x} - 2xe^{-x}$

Apply $y(0) = -1$, $y'(0) = 1$

$$y'(x) = C_1 e^x - C_2 e^{-x} - 2e^{-x} + 2xe^{-x}$$

$$y(0) = C_1 e^0 + C_2 e^0 - 2 \cdot 0 e^0 = -1$$

$$C_1 + C_2 = -1$$

$$y'(0) = C_1 e^0 - C_2 e^0 - 2e^0 + 2 \cdot 0 e^0 = 1$$

$$C_1 - C_2 - 2 = 1$$

$$C_1 - C_2 = 3$$

$$C_1 + C_2 = -1$$

add

$$C_1 - C_2 = 3$$

$$2C_1 = 2 \Rightarrow C_1 = 1, C_2 = -2$$

The solution to the IVP is

$$y = e^x - 2e^{-x} - 2xe^{-x}$$
