Section 13: The Laplace Transform

Definition: Let $f(t)$ be defined on $[0, \infty)$. The Laplace transform of f is denoted and defined by

$$\mathscr{L}\{f(t)\} = \int_0^\infty e^{-st} f(t)\, dt = F(s).$$

The domain of the transformation $F(s)$ is the set of all s such that the integral is convergent.

The Laplace Transform is a Linear Transformation

Some basic results include:

- $\mathscr{L}\{\alpha f(t) + \beta g(t)\} = \alpha F(s) + \beta G(s)$

- $\mathscr{L}\{1\} = \frac{1}{s}, \quad s > 0$

- $\mathscr{L}\{t^n\} = \frac{n!}{s^{n+1}}, \quad s > 0$ for $n = 1, 2, \ldots$

- $\mathscr{L}\{e^{at}\} = \frac{1}{s-a}, \quad s > a$

- $\mathscr{L}\{\cos kt\} = \frac{s}{s^2+k^2}, \quad s > 0$

- $\mathscr{L}\{\sin kt\} = \frac{k}{s^2+k^2}, \quad s > 0$

Evaluate the Laplace transform $\mathscr{L}\{f(t)\}$ if

(d) $f(t) = \sin^2 5t$

$\mathscr{L}\{\cos kt\} = \frac{s}{s^2+k^2}$,

$\mathscr{L}\{\sin kt\} = \frac{k}{s^2+k^2}$,

$f(t) = \frac{1}{2} - \frac{1}{2} \cos(10t)$

$\mathscr{L}\{f(t)\} = \mathscr{L}\{\frac{1}{2}\} - \mathscr{L}\{\frac{1}{2}\cos(5t)\}$

$= \frac{1}{2}\mathscr{L}\{1\} - \frac{1}{2}\mathscr{L}\{\cos(5t)\}$

$= \frac{1}{2}\left(\frac{1}{s}\right) - \frac{1}{2}\frac{s}{s^2+10^2} = \frac{1}{2s} - \frac{1}{2}\frac{s}{s^2+100}$

How would we integrate $\int \sin^2(5t)\,dt$?

Wed use $\quad \sin^2\theta = \frac{1}{2} - \frac{1}{2}\cos(2\theta)$

Sufficient Conditions for Existence of $\mathscr{L}\{f(t)\}$

Definition: Let $c > 0$. A function f defined on $[0, \infty)$ is said to be of *exponential order c* provided there exists positive constants M and T such that $|f(t)| < Me^{ct}$ for all $t > T$.

f grows no faster than an exponential function

Definition: A function f is said to be *piecewise continuous* on an interval $[a, b]$ if f has at most finitely many jump discontinuities on $[a, b]$ and is continuous between each such jump.

Sufficient Conditions for Existence of $\mathscr{L}\{f(t)\}$

Theorem: If f is piecewise continuous on $[0, \infty)$ and of exponential order c for some $c > 0$, then f has a Laplace transform for $s > c$.

An example of a function that is NOT of exponential order for any c is $f(t) = e^{t^2}$. Note that

$$f(t) = e^{t^2} = \left(e^t\right)^t \quad \implies \quad |f(t)| > e^{ct} \quad \text{whenever} \quad t > c.$$

This is a function that doesn't have a Laplace transform. We won't be dealing with this type of function here.

Section 14: Inverse Laplace Transforms

Now we wish to go *backwards*: Given $F(s)$ can we find a function $f(t)$ such that $\mathscr{L}\{f(t)\} = F(s)$?

If so, we'll use the following notation

$$\mathscr{L}^{-1}\{F(s)\} = f(t) \quad \text{provided} \quad \mathscr{L}\{f(t)\} = F(s).$$

We'll call $f(t)$ an inverse Laplace transform of $F(s)$.

A Table of Inverse Laplace Transforms

- $\mathscr{L}^{-1}\left\{\frac{1}{s}\right\} = 1$

- $\mathscr{L}^{-1}\left\{\frac{n!}{s^{n+1}}\right\} = t^n$, for $n = 1, 2, \ldots$

- $\mathscr{L}^{-1}\left\{\frac{1}{s-a}\right\} = e^{at}$

- $\mathscr{L}^{-1}\left\{\frac{s}{s^2+k^2}\right\} = \cos kt$

- $\mathscr{L}^{-1}\left\{\frac{k}{s^2+k^2}\right\} = \sin kt$

The inverse Laplace transform is also linear so that

$$\mathscr{L}^{-1}\{\alpha F(s) + \beta G(s)\} = \alpha f(t) + \beta g(t)$$

Using a Table

When using a table of Laplace transforms, the expression must match exactly. For example,

$$\mathscr{L}\left\{t^n\right\} = \frac{n!}{s^{n+1}}$$

so

$$\mathscr{L}^{-1}\left\{\frac{3!}{s^4}\right\} = t^3.$$

Note that $n = 3$, so there must be 3! in the numerator and the power $4 = 3 + 1$ on s.

Find the Inverse Laplace Transform

$$\mathscr{L}^{-1}\left\{\frac{n!}{s^{n+1}}\right\} = t^n.$$

(a) $\mathscr{L}^{-1}\left\{\dfrac{1}{s^7}\right\}$

we need $\dfrac{6!}{s^7}$ to match the table exactly.

Note: $\dfrac{1}{s^7} = \dfrac{6!}{6!} \cdot \dfrac{1}{s^7} = \dfrac{1}{6!} \dfrac{6!}{s^7}$

$\mathscr{L}^{-1}\left\{\dfrac{1}{s^7}\right\} = \mathscr{L}^{-1}\left\{\dfrac{1}{6!} \dfrac{6!}{s^7}\right\} = \dfrac{1}{6!} \mathscr{L}^{-1}\left\{\dfrac{6!}{s^7}\right\} = \dfrac{1}{6!} t^6$

Example: Evaluate

$$\mathscr{L}^{-1}\left\{\frac{s}{s^2+k^2}\right\} = \cos kt$$

(b) $\mathscr{L}^{-1}\left\{\dfrac{s+1}{s^2+9}\right\}$

$$\mathscr{L}^{-1}\left\{\frac{k}{s^2+k^2}\right\} = \sin kt$$

$= \mathscr{L}^{-1}\left\{\dfrac{s}{s^2+9} + \dfrac{1}{s^2+9}\right\}$

$= \mathscr{L}^{-1}\left\{\dfrac{s}{s^2+3^2}\right\} + \mathscr{L}^{-1}\left\{\dfrac{1}{s^2+3^2}\right\}$

$= \mathscr{L}^{-1}\left\{\dfrac{s}{s^2+3^2}\right\} + \dfrac{1}{3}\mathscr{L}^{-1}\left\{\dfrac{3}{s^2+3^2}\right\}$

$= \cos(3t) + \dfrac{1}{3}\sin(3t)$

Example: Evaluate

(c) $\mathscr{L}^{-1}\left\{\dfrac{s-8}{s^2-2s}\right\}$

We'll do a partial fraction decomp.

$$\frac{s-8}{s^2-2s} = \frac{s-8}{s(s-2)} = \frac{A}{s} + \frac{B}{s-2}$$

Clear fractions

$$s-8 = A(s-2) + Bs$$

set

$s=0 \qquad 0-8 = A(0-2) + B(0) \implies -8 = -2A \implies A = 4$

$s=2 \qquad 2-8 = A(2-2) + B(2) \implies -6 = 2B \implies B = -3$

$$\frac{s-8}{s^2-2s} = \frac{4}{s} - \frac{3}{s-2}$$

$$\mathscr{L}^{-1}\left\{\frac{s-8}{s^2-2s}\right\} = \mathscr{L}^{-1}\left\{\frac{4}{s} - \frac{3}{s-2}\right\}$$

$$= 4\,\mathscr{L}^{-1}\left\{\frac{1}{s}\right\} - 3\,\mathscr{L}^{-1}\left\{\frac{1}{s-2}\right\}$$

$$= 4(1) - 3\,e^{2t}$$

$$= 4 - 3\,e^{2t}$$
