Section 15: Shift Theorems

Theorem: Suppose $\mathcal{L}\{f(t)\} = F(s)$. Then for any real number a $\mathcal{L}\{e^{at}f(t)\} = F(s-a).$

We can state this in terms of the inverse transform. If F(s) has an inverse Laplace transform, then

$$\mathscr{L}^{-1}\{F(s-a)\}=e^{at}\mathscr{L}^{-1}\{F(s)\}.$$

The Unit Step Function

Let $a \ge 0$. The unit step function $\mathcal{U}(t-a)$ is defined by

$$\mathscr{U}(t-a) = \left\{ \begin{array}{ll} 0, & 0 \le t < a \\ 1, & t \ge a \end{array} \right.$$

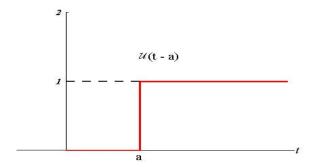

Figure: We can use the unit step function to provide convenient expressions for piecewise defined functions.

Piecewise Defined Functions

We can use the unit step function to write piecewise defined functions in a format convenient for taking Laplace transforms. For example, suppose $0 < a < b < \infty$ and

$$f(t) = \begin{cases} f_1(t), & 0 \le t < a \\ f_2(t), & a \le t < b \\ f_3(t), & b \le t < \infty \end{cases}$$

We can write f in the form

$$f(t) = f_1(t) - f_1(t)\mathcal{U}(t-a) + f_2(t)\mathcal{U}(t-a) - f_2(t)\mathcal{U}(t-b) + f_3(t)\mathcal{U}(t-b)$$

$$= f_1(t)(1-u(t-a)) + f_2(t)(u(t-a)-u(t-b)) + f_3(t)u(t-b)$$

Translation in t

Given a function f(t) for $t \ge 0$, and a number a > 0

$$f(t-a)\mathscr{U}(t-a) = \left\{ \begin{array}{ll} 0, & 0 \leq t < a \\ f(t-a), & t \geq a \end{array} \right..$$

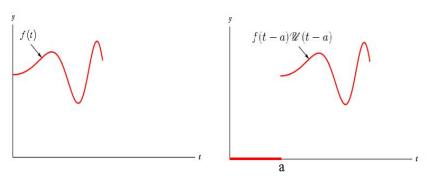

Figure: The function $f(t-a)\mathcal{U}(t-a)$ has the graph of f shifted a units to the right with value of zero for t to the left of a.

Find $\mathcal{L}\{\mathcal{U}(t-a)\}\$ for a>0.

By definition,

$$\mathscr{L}\left\{\mathscr{U}(t-a)\right\} = \int_0^\infty e^{-st} \mathscr{U}(t-a) dt$$

$$= \int_{0}^{a} e^{-st} u(t-a) dt + \int_{0}^{a} e^{-st} u(t-a) dt$$

$$= \int_{0}^{a} e^{-st} (0) dt + \int_{0}^{a} e^{-st} (1) dt$$

$$= \int_{0}^{a} e^{-st} (0) dt + \int_{0}^{a} e^{-st} (1) dt$$

$$= \int_{0}^{a} e^{-st} (0) dt + \int_{0}^{a} e^{-st} (1) dt$$

$$= \int_{0}^{a} e^{-st} u(t-a) dt$$

$$= \frac{1}{-5} e^{-st} |_{\alpha}^{\infty}$$

$$\mathscr{U}(t-a) = \left\{ \begin{array}{ll} 0, & 0 \le t < a \\ 1, & a \le t < \infty \end{array} \right.$$

5/15

$$=\frac{1}{S}\left(0-\frac{-s(a)}{S}\right)=\frac{e^{-as}}{S}$$

Theorem (translation in *t*)

If
$$F(s)=\mathscr{L}\{f(t)\}$$
 and $a>0$, then
$$\mathscr{L}\{f(t-a)\mathscr{U}(t-a)\}=e^{-as}F(s).$$

A special case is f(t) = 1. We just found

$$\mathscr{L}\{\mathscr{U}(t-a)\}=e^{-as}\mathscr{L}\{1\}=\frac{e^{-as}}{s}.$$

We can state this in terms of the inverse transform as

$$\mathscr{L}^{-1}\{e^{-as}F(s)\}=f(t-a)\mathscr{U}(t-a).$$
 Where $f(t)=\hat{\mathcal{J}}(F(s))$

Example

Find the Laplace transform $\mathcal{L}\{f(t)\}$ where

$$f(t) = \begin{cases} 1, & 0 \le t < 1 \\ t, & t \ge 1 \end{cases}$$

(a) First write *f* in terms of unit step functions.

$$f(t) = 1 - 1u(t-1) + tu(t-1)$$

Let's collect like terms
 $f(t) = 1 + (-1 + t)u(t-1)$
 $f(t) = 1 + (t-1)u(t-1)$

Example Continued...

(b) Now use the fact that $f(t) = 1 + (t-1)\mathcal{U}(t-1)$ to find $\mathcal{L}\{f\}$.

If
$$f_{i}(t) = t$$
 then $f_{i}(t-1) = t-1$ and
$$\mathcal{L}(t) = \frac{1}{S^{2}} = F(S)$$

Alternative Form for Translation in t

It is often the case that we wish to take the transform of a product of the form

$$g(t)\mathscr{U}(t-a)$$

in which the function *g* is not translated.

The main theorem statement

$$\mathscr{L}\{f(t-a)\mathscr{U}(t-a)\}=e^{-as}F(s).$$

can be restated as

$$\mathscr{L}\{g(t)\mathscr{U}(t-a)\}=e^{-as}\mathscr{L}\{g(t+a)\}.$$

This is based on the observation that

$$g(t) = g((t+a)-a).$$

Example

$$\mathscr{L}\{g(t)\mathscr{U}(t-a)\}=e^{-as}\mathscr{L}\{g(t+a)\}$$

Example: Find
$$\mathcal{L}\{\cos t \mathcal{U}\left(t-\frac{\pi}{2}\right)\} = e^{-\frac{\pi}{2}s} \mathcal{L}\left(\cos\left(t+\frac{\pi}{2}\right)\right)$$

$$= e^{-\frac{\pi}{2}s} \mathcal{L}(-s_{n+1})$$

$$= -e^{-\frac{\pi}{2}s} \left(\frac{1}{s^{2}+1^{2}}\right) = \frac{-e^{\frac{\pi}{2}s}}{s^{2}+1}$$

$$Cos(t+\frac{\pi}{2}) = Cost Cos \frac{\pi}{2} - Sint Sin \pi/2 = -Sint$$

Example

$$\mathscr{L}^{-1}\{e^{-as}F(s)\}=f(t-a)\mathscr{U}(t-a)$$

Example: Find
$$\mathcal{L}^{-1}\left\{\frac{e^{-2s}}{s(s+1)}\right\} = \mathcal{L}^{-1}\left\{\frac{e^{-2s}}{s(s+1)}\right\}$$

$$F(s) = \frac{1}{S(s+1)} \text{ we need } f(t) = \hat{\mathcal{L}} \left(F(s) \right)$$

$$\text{partial fraction}$$

$$\frac{1}{S(s+1)} = \frac{A}{S} + \frac{P}{S+1} \implies 1 = A(S+1) + BS$$

$$S = 0 \qquad 1 = A$$

$$S = 0 \qquad 1 = -B$$

$$F(s) = \frac{1}{S} - \frac{1}{S+1}$$

$$\tilde{\mathcal{J}}\left(\frac{1}{5} - \frac{1}{5+1}\right) = \tilde{\mathcal{J}}'\left(\frac{1}{5}\right) - \tilde{\mathcal{L}}'\left(\frac{1}{5+1}\right) \\
= 1 - \tilde{e}^{t}$$

$$\mathscr{L}^{-1}\{e^{-as}F(s)\}=f(t-a)\mathscr{U}(t-a)$$

$$\mathcal{L}^{-1}\left\{\frac{e^{-2s}}{s(s+1)}\right\} = \tilde{\mathcal{L}}\left\{\frac{e^{-2s}}{e^{-2s}}\right\}$$

$$= \left(1 - e^{\left(t-2\right)}\right) \mathcal{U}\left(t-2\right)$$
